## Introduction

Safe drinking water is fundamental to everyday life. The goal of SIM.8.10P is to determine state of the practice in SIM countries for the determination of trace elements in water. This report summarizes the results of two intercomparison exercises, SIM 8.10P, Part I and Part II, organized in 2003 and 2004. These were co-ordinated by the

Chemical Metrology Group of the Institute for National Measurement Standards (INMS) of the National Research Council Canada (NRCC). SIM 8.10P is a follow-up to SIM.8.P2, conducted between October 1999 and September 2000 and co-ordinated by the National Institute of Standards and Technology (NIST), USA.

## Participation in SIM.8.10P

Table 1 presents the timetable for SIM 8.10P, Part I and Part II. A call for participation was sent out to each country within the SIM Region. Laboratories were asked to respond directly to NRCC with their intention to participate. In addition to NMIs within SIM or their official designees, several additional laboratories were included in the exercise. The samples were distributed by courier from NRCC. The deadline for the submission of results for each exercise is listed in Table 1.

Laboratories were permitted to use their analytical method of choice to determine the primary elements for this study: Cr, Fe, Ni, Cu, Zn, As, Cd, Ba, and Pb. A full uncertainty budget in accordance with the GUM [1] was also requested from the participants. Table 2 lists the participants in SIM.8.10P. Seventeen laboratories participated in both Part I and Part II, four and six laboratories participated in only Part I and Part II, respectively.

**Table 1. Schedule for SIM.8.10P.**

Timeline	Part I	Part II
Call for participation	8-Mar-03	1-Apr-04
Sample distribution	8-May-03	30-Apr-04
Deadline for reporting results	5-Sep-03	20-Sep-04
Results presented at SIM	26-Nov-03	3-Nov-04
Follow up workshop	5-Feb-04	-

**Table 2. Participants in SIM.8.10P.**

INDICASAT / SENACYT	Panamá	Félix Rodríguez

## Sample Preparation

Samples were prepared in-house at NRCC. Two 25 liter LDPE carboys were cleaned with 10 % (v/v) high purity nitric acid for 72 hours. Each carboy was emptied, rinsed with high purity water and refilled with 18 liters of bottled natural spring water (Labrador Laurentienne Inc., Quebec, Canada). This water was packaged in 18 liter plastic containers and distributed for use with water dispensers. The samples were acidified by addition of 100 ml of NRC sub-boiled high purity nitric acid. Samples were fortified with Cr, Fe, Ni, Cu, Zn, As, Cd, Ba, and Pb by adding appropriate amounts of 1000 µg/ml stock solutions (ICP Grade, SCP Science, Montreal, Quebec) prepared from high purity materials and traceable to NIST. Samples A and B were distributed as in Part I and Samples C and D in Part II. The fortified

concentrations for Sample A and Sample C were chosen to approach the maximum acceptable limits of the USEPA and Canadian government guidelines for drinking water [2,3]. The fortified concentrations for Sample B and Sample D were approximately 10- fold greater. The resulting solutions were thoroughly mixed and sampled into precleaned 250 mL HDPE bottles.

A homogeneity test for all elements was performed on six randomly selected samples. In all cases, the coefficient of variation was less than 1.2% with the exception of As (3%). The latter measurement represented variation inherent to the analytical technique used (ETAAS) rather than reflecting between bottle differences. The material was deemed stable for at least one year at room temperature based on NRCC experience with similar samples.

## Results

The majority of results for Part I and Part II were received by the respective deadlines. The submitted results were compiled in a database and a copy was returned by email to the participants for verification that no transcription errors had occurred. A few minor changes were made.

In Part I, Laboratories 2, 20 and 21 submitted two independent results based on alternative detection methodologies. In such cases, the independent results are listed separately and are delineated as the laboratory number accompanied by an alphabetical suffix.

Graphical representation of the results are presented on pages 8 to 43. The mean is shown as a square, and vertical error bars represent the reported expanded uncertainty. The assigned value is displayed as a solid horizontal line. Divergent data that would

distort the graph are indicated with an arrow head near the graph's upper border.

A table below the graph for each samples lists: the recommended values, uncertainties and instrumental techniques reported by the participants. As well, the source of the assigned value and, for comparative purposes, a summary of submitted results, is also provided for each sample. In some cases, obvious outliers were subjectively rejected from the overall summary.

Appendix A lists the submitted data: the mean, uncertainty and maximum of six values for each laboratory. For Samples C and D a "U" following the uncertainty indicates that the laboratory reported an uncertainty value, otherwise, the uncertainty in the data is represented as a standard deviation of the replicate results.

## Assigned Values

### Part I

The assigned values for Part I of this exercise were determined from results submitted by laboratories having successful BIPM/CIPM experience. Thus, SIM.8.10P could provide international comparability for trace element analysis in drinking water by linking intercomparison results for SIM nations with BIPM/CIPM key comparison participants. However, this restriction limited only data submitted by NRCC and PTB for calculation of the SIM.8.P10 Part I assigned values. In some cases, NRCC and PTB were able to employ the method of isotope dilution sector field inductively coupled plasma mass spectrometry (ID-SF-ICP-MS). The use of isotope dilution as a calibration method is considered a primary method when properly employed. Unfortunately, for monoisotopic elements or elements suffering severe interferences, other techniques must be used.

The assigned values for Cr, Cu and Ni were calculated based on NRCC results using alternative methods of detection, such as inductively coupled atomic emission (ICP-AES) and electrothermal atomization atomic absorption (ETAAS). For As and Fe, the assigned value was based on only one NRCC method.

### Part II

The assigned values in the follow up exercise were based on gravimetric calculations where possible. The exception was Ba in both Sample C and D and Ni in Sample C where analysis of the unspiked spring water found levels of analyte naturally present that could not be considered negligible. In these cases the NRCC values was used for comparative purposes.

## Uncertainties

The majority of laboratories reported results with an uncertainty value calculated according to the principles outlined in the GUM [1]. Only a few participants included in their report details of the uncertainty budget calculation.

Some laboratories did not state whether the uncertainty reported was an expanded uncertainty i.e., multiplied by the coverage factor,  $k$ .

Major sources contributing to overall uncertainty identified by several participants were calibration and dilution factors.

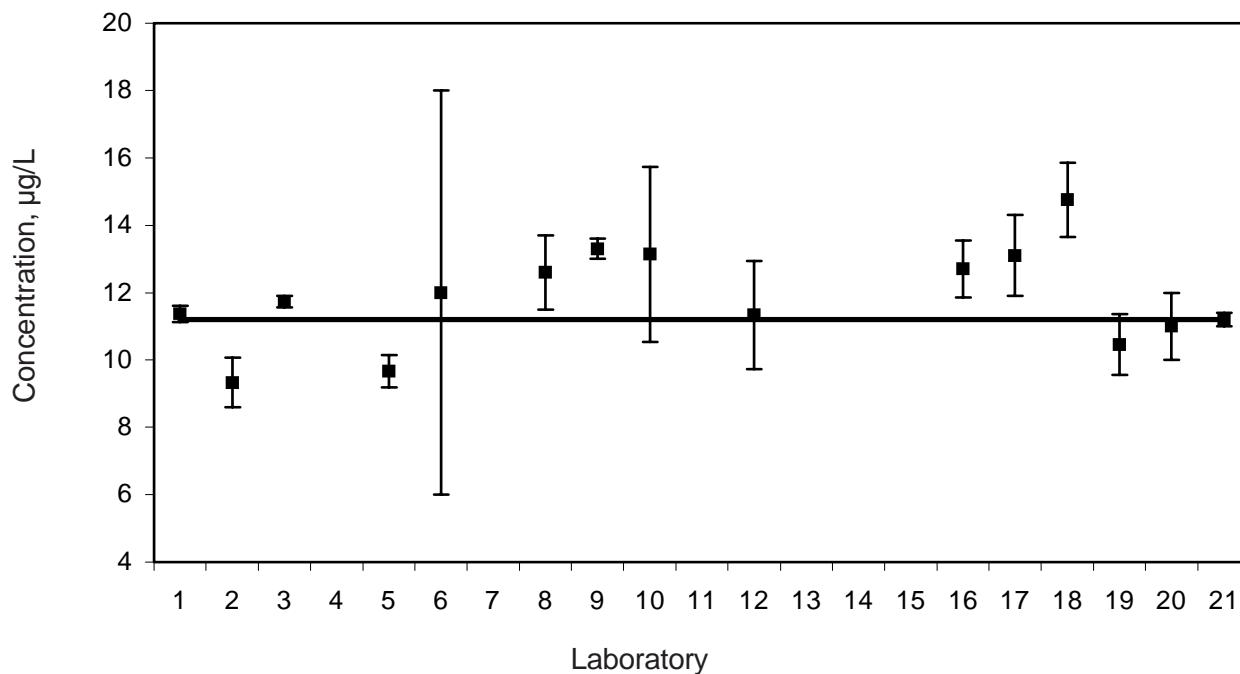

## Workshop

Following each of these two exercises the results were discussed by the participants at workshops in Caracas (November 2003), Costa Rica (February 2004) and Margarita Is. Venezuela (November 2004).

Participants were encouraged to attend and make a brief presentation outlining their measurement method and model for calculating measurement uncertainty.

## Chromium

## Part I Sample A

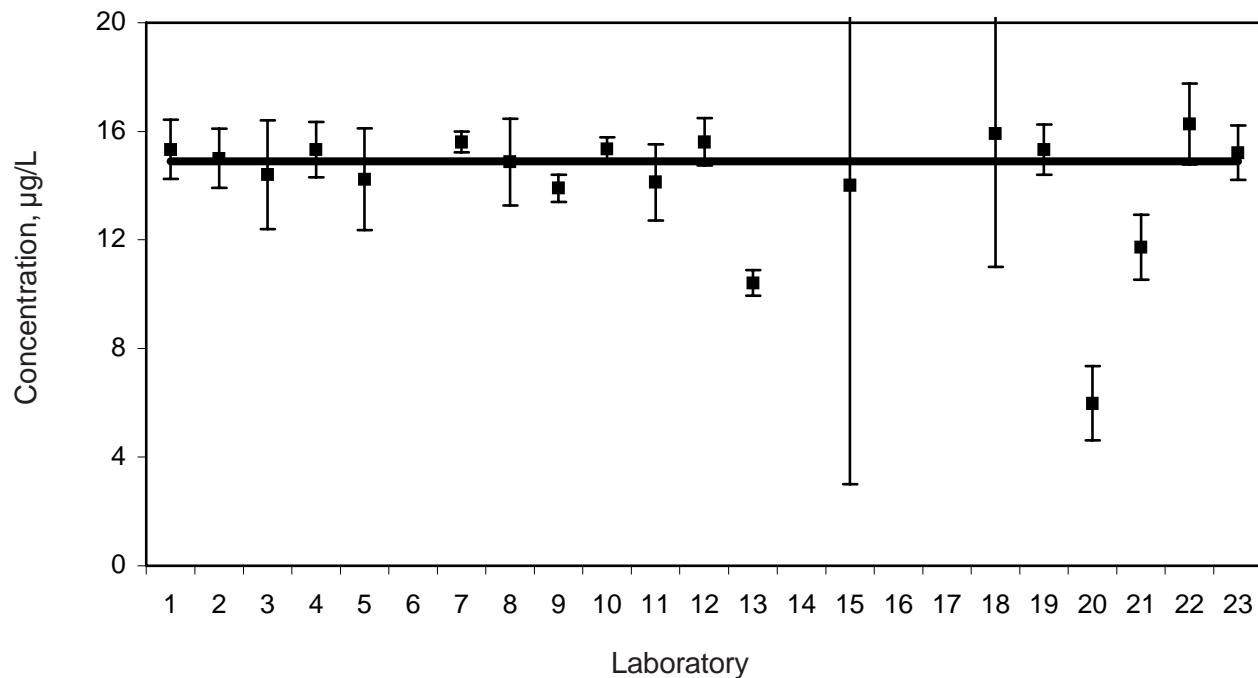

Lab	Reported Value, µg/L	Uncertainty, µg/L	Technique

### Assigned Value

A value of 83.2 µg/L was assigned to Cr in Sample D based on the gravimetric calculation.

Overall Summary	
No. of results	21
Mean	81.6
Median	82.4
Sample S.D.	9.9
95% C.I.	5.2
gravimetric	83.2

## Conclusions

It is clear from Part I of this study that for a few laboratories accuracy is difficult to achieve for the analysis of trace elements in drinking water at these concentration levels. Results were generally closer to the assigned values for Part II. Only a few laboratories were able to use multiple analytical techniques; thus one might question the use of ICP-AES for some low level metal analysis or the application of ETAAS for the higher concentrations. The concept of "fit for purpose" should be given more consideration.

In a few cases, unrealistic uncertainty budgets were submitted for Part I, but many laboratories made commendable attempts to submit data based on the concept of the GUM for Part II.
